

case study

A client approval portal, built end to end.

Relaydesk is a sample SaaS MVP: studios share work, clients approve it or mark it up from their phone, and every version and every “yes” is kept. It has a live demo anyone can click through.

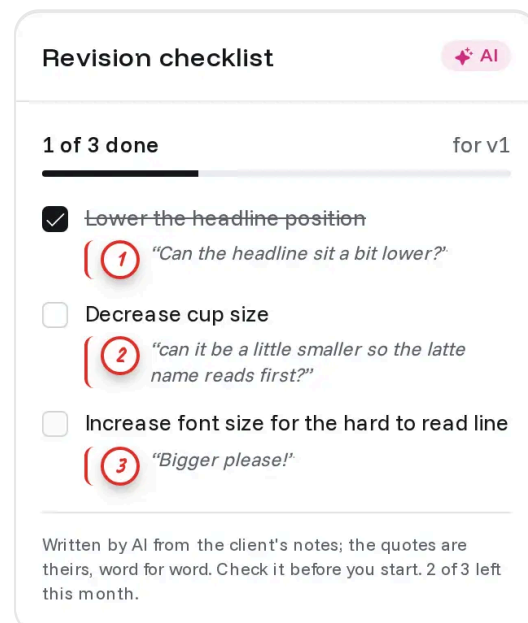

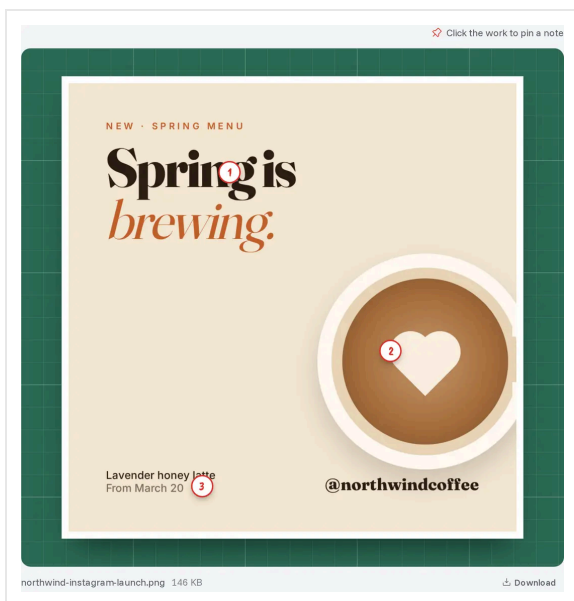

Sample project: the companies, people and data are fictional, and payments run in Stripe test mode.

The problem

Small studios send work to clients and then chase approval across email, chat and shared drives. Feedback gets lost, nobody is sure which version is final, and invoices wait on a “looks good” that never arrives in writing.

What was built

- ✓ **Studios, roles and invites**
Owner, teammate and client roles. One-time invite links; only a hash of each is stored.
- ✓ **Approvals and comments**
Clients approve or request changes from any phone. Every decision is recorded with a name and date.
- ✓ **Stripe billing**
Free, Pro and Studio plans. Verified webhooks, recorded once; plans update the moment checkout finishes.
- ✓ **Admin panel**
Studios, test-mode revenue, the webhook log and an audit log. Suspending a studio is enforced in the database.
- ✓ **Search, nudges, notifications**
Ctrl/⌘K search, ready-made reminders for late clients, and a notification bell.
- ✓ **Versioned deliverables**
Every upload is a new version in private storage, opened through short-lived signed links.
- ✓ **Pins and version compare**
Clients tap the work to pin a note. A slider wipes between versions.
- ✓ **AI revision checklist**
Client notes become a to-do list. Every quote is the client's own words, checked against the database.
- ✓ **Sign-off sheet**
A printable approval record with the SHA-256 fingerprint of the exact file that was approved.
- ✓ **A private demo for every visitor**
Each "try it" click gets its own seeded copy, deleted after 24 hours.

How it's built

App

Next.js 16 (App Router, Server Components and Server Actions), TypeScript, Tailwind, deployed on Vercel.

Payments

Stripe Checkout and Customer Portal. Webhooks are signature-checked, re-fetched from Stripe and recorded once.

Quality

pgTAP database tests and Playwright end-to-end tests run in GitHub Actions on every push.

Data and auth

Supabase Postgres with Row Level Security on every table, private file storage and signed links.

AI

Google Gemini through the Vercel AI SDK, with a monthly quota per plan enforced in the database.

Docs

A written blueprint: users, features with a clear "done", data model, security plan, decisions and costs.

Proof, not promises

82

database tests check who can read and change what, across studios, clients and plans.

14

end-to-end tests click through the whole app, including on a phone, on every push.

96

Lighthouse performance on mobile, with 96 accessibility and 100 best practices.

0

secrets in the browser or the repo. Keys live only in Vercel and a git-ignored local file.

Lighthouse SEO reads low on purpose: a fictional product is kept out of search engines with a no-index tag. Every other SEO check passes.

How the work was done

Built with AI coding tools (Claude Code) for speed, with every change reviewed and tested before it shipped. The scope was written first, each feature was finished before the next began. On client projects, the code, database and deployment live in the client's own accounts from day one.
